Introduction

Particle physics is a remarkably successful field of scientific inquiry. The ability to precisely predict the properties of a exceedingly wide range of physical phenomena, such as the description of the cosmic microwave background [1, 2], the understanding of the anomalous magnetic dipole moment of the electron [3, 4], and the measurement of the number of weakly-interacting neutrino flavors [5] is truly amazing.

The theory that has allowed this range of predictions is the *Standard Model* of particle physics (SM). The Standard Model combines the electroweak theory of Glashow, Weinberg, and Salam [6–8] with the theory of the strong interactions, as first envisioned by Gell-Mann and Zweig [9, 10]. This quantum field theory (QFT) contains a tiny number of particles, whose interactions describe phenomena up to at least the TeV scale. These particles are manifestations of the fields of the Standard Model, after application of the Higgs Mechanism. The particle content of the SM consists only of the six quarks, the six leptons, the four gauge bosons, and the scalar Higgs boson.

Despite its impressive range of described phenomena, the Standard Model has some theoretical and experimental deficiencies. The SM contains 26 free parameters¹. It would be more theoretically pleasing to understand these free parameters in terms of a more fundamental theory. The major theoretical concern of the Standard Model, as it pertains to this thesis, is the *hierachy problem*[11–15]. The light mass

¹This is the Standard Model corrected to include neutrino masses. These parameters are the fermion masses (6 leptons, 6 quarks), CKM and PMNS mixing angles (8 angles, 2 CP-violating phases), W/Z/Higgs masses (3), the Higgs field expectation value, and the couplings of the strong, weak, and electromagnetic forces (3 α_{force}).

81 of the Higgs boson (125 GeV) should be quadratically dependent on the scale of UV
 82 physics, due to the quantum corrections from high-energy physics processes. The
 83 most perplexing experimental issue is the existence of *dark matter*, as demonstrated
 84 by galactic rotation curves [16–22]. This data has shown that there exists additional
 85 matter which has not yet been seen interacting with the particles of the Standard
 86 Model. There is no particle in the SM which can act as a candidate for dark matter.

87 Both of these major issues, as well as numerous others, can be solved by the
 88 introduction of *supersymmetry* (SUSY) [15, 23–33]. In supersymmetric theories, each
 89 SM particles has a so-called *superpartner*, or sparticle partner, differing from given SM
 90 particle by 1/2 in spin. These theories solve the hierarchy problem, since the quantum
 91 corrections induced from the superpartners exactly cancel those induced by the SM
 92 particles. In addition, these theories are usually constructed assuming R -parity,
 93 which can be thought of as the “charge” of supersymmetry, with SM particles having
 94 $R = 1$ and sparticles having $R = -1$. In collider experiments, since the incoming
 95 SM particles have total $R = 1$, the resulting sparticles are produced in pairs. This
 96 produces a rich phenomenology, which is characterized by significant hadronic activity
 97 and large missing transverse energy (E_T^{miss}), which provide significant discrimination
 98 against SM backgrounds [34].

99 Despite the power of searches for supersymmetry where E_T^{miss} is a primary dis-
 100 criminating variable, there has been significant interest in the use of other variables
 101 to discriminate against SM backgrounds. These include searches employing variables
 102 such as αT , $M_{T,2}$, and the razor variables (M_R, R^2) [35–45]. In this thesis, we will
 103 present the first search for supersymmetry using the novel Recursive Jigsaw Recon-
 104 struction (RJR) technique. RJR can be considered the conceptual successor of the
 105 razor variables. We impose a particular final state “decay tree” on an events, which
 106 roughly corresponds to a simplified Feynmann diagram in decays containing weakly-
 107 interacting particles. We account for the missing degrees of freedom associated to

108 the weakly-interacting particles by a series of simplifying assumptions, which allow
109 us to calculate our variables of interest at each step in the decay tree. This allows an
110 unprecedented understanding of the internal structure of the decay and the ability to
111 construct additional variables to reject Standard Model backgrounds.

112 This thesis details a search for the superpartners of the gluon and quarks, the
113 gluino and squarks, in final states with zero leptons, with 13.3 fb^{-1} of data using the
114 ATLAS detector. We organize the thesis as follows. The theoretical foundations of
115 the Standard Model and supersymmetry are described in Chapters 2 and 3. The
116 Large Hadron Collider and the ATLAS detector are presented in Chapters 4 and 5.
117 Chapter 5 provides a detailed description of Recursive Jigsaw Reconstruction and a
118 description of the variables used for the particular search presented in this thesis.
119 Chapter 6 presents the details of the analysis, including details of the dataset, object
120 reconstruction, and selections used. In Chapter 7, the final results are presented;
121 since there is no evidence of a supersymmetric signal in the analysis, we present the
122 final exclusion curves in simplified supersymmetric models.

124

The Standard Model

125 Here you can write some introductory remarks about your chapter. I like to give each
 126 sentence its own line.

127 When you need a new paragraph, just skip an extra line.

128 **2.1 Quantum Field Theory**

129

130 In this section, we provide a brief overview of the necessary concepts from Quan-
 131 tum Field Theory (QFT).

132 In modern physics, the laws of nature are described by the “action” S , with the
 133 imposition of the principle of minimum action. The action is the integral over the
 134 spacetime coordinates of the “Lagrangian density” \mathcal{L} , or Lagrangian for short. The
 135 Lagrangian is a function of “fields”; general fields will be called $\phi(x^\mu)$, where the
 136 indices μ run over the space-time coordinates. We can then write the action S as

$$S = \int d^4x \mathcal{L}[\phi_i(x^\mu), \partial_\mu \phi_i(x^\mu)] \quad (2.1)$$

137 where we have an additional summation over i (of the different fields). Generally,
 138 we impose the following constraints on the Lagrangian :

- 139 1. Translational invariance - The Lagrangian is only a function of the fields ϕ and
 140 their derivatives $\partial_\mu \phi$
- 141 2. Locality - The Lagrangian is only a function of one point x_μ in spacetime.

cite Yuval's
lectures and
notes some-
how

cite

- 142 3. Reality condition - The Lagrangian is real to conserve probability.
- 143 4. Lorentz invariance - The Lagrangian is invariant under the Poincaré group of
144 spacetime.
- 145 5. Analyticity - The Lagrangian is an analytical function of the fields; this is to
146 allow the use of perturbation theory.
- 147 6. Invariance and Naturalness - The Lagrangian is invariant under some internal
148 symmetry groups; in fact, the Lagrangian will have *all* terms allowed by the
imposed symmetry groups.
maybe add in ref here
- 150 7. Renormalizability - The Lagrangian will be renormalizable - in practice, this
151 means there will not be terms with more than power 4 in the fields.

152 The key item from the point of view of this thesis is that of “Invariance and
153 Natural”. We impose a set of “symmetries” and then our Lagrangian is the most
154 general which is allowed by those symmetries.

155 2.2 Symmetries

156 Symmetries can be seen as the fundamental guiding concept of modern physics. Sym-
cite? 157 metries are described by “groups”. . To illustrate the importance of symmetries and
158 their mathematical description, groups, we start here with two of the simplest and
159 most useful examples : \mathbb{Z}_2 and $U(1)$.

160 \mathbb{Z}_2 symmetry

161 \mathbb{Z}_2 symmetry is the simplest example of a “discrete” symmetry. Consider the most
162 general Lagrangian of a single real scalar field $\phi(x_\mu)$:

$$\mathcal{L}_\phi = \frac{1}{2}\partial_\mu\phi\partial^\mu\phi - \frac{m^2}{2}\phi^2 - \frac{\mu}{2\sqrt{2}}\phi^3 - \lambda\phi^4 \quad (2.2)$$

Now we *impose* the symmetry :

$$\mathcal{L}(\phi) = \mathcal{L}(-\phi) \quad (2.3)$$

163 This has the effect of restricting the allowed terms of the Lagrangian. In particular,
 164 we can see the term $\phi^3 \rightarrow -\phi^3$ under the symmetry transformation, and thus must
 165 be disallowed by this symmetry. This means under the imposition of this particular
 166 symmetry, our Lagrangian should be rewritten as :

$$\mathcal{L}_\phi = \frac{1}{2}\partial_\mu\phi\partial^\mu\phi - \frac{m^2}{2}\phi^2 - \lambda\phi^4 \quad (2.4)$$

167 The effect of this symmetry is that the total number of ϕ particles can only change
 168 by even numbers, since the only interaction term $\lambda\phi^4$ is an even power of the field.
 169 This symmetry is often imposed in supersymmetric theories, as we will see in Chapter
 170 3.

171 **$U(1)$ symmetry**

172 $U(1)$ is the simplest example of a “continuous” (or Lie) group. Now consider a theory
 173 with a single complex scalar field $\phi = \text{Re } \phi + i \text{Im } \phi$:

$$\mathcal{L}_\phi = \delta_{i,j}\frac{1}{2}\partial_\mu\phi_i\partial^\mu\phi_j - \frac{m^2}{2}\phi_i\phi_j - \frac{\mu}{2\sqrt{2}}\phi_i\phi_j\phi_k - \lambda\phi_i\phi_j\phi_k\phi_l \quad (2.5)$$

174 where $i, j, k, l = \text{Re}, \text{Im}$. In this case, we impose the following $U(1)$ symmetry
 175 : $\phi \rightarrow e^{i\theta}\phi, \phi^* \rightarrow e^{-i\theta}\phi^*$. We see immediately that this again disallows the third-order
 176 terms, and we can write a theory of a complex scalar field with $U(1)$ symmetry as :

$$\mathcal{L}_\phi = \partial_\mu\phi\partial^\mu\phi^* - \frac{m^2}{2}\phi\phi^* - \lambda(\phi\phi^*)^2 \quad (2.6)$$

$$\phi \rightarrow e^{i\theta} \phi \tag{2.7}$$
